

Analysis and Design of Algorithms

Divide and Conquer

Divide & Conquer

It is an **algorithmic paradigm** in which the problem is solved by following **3 main steps**:

Divide

Conquer

Combine

Divide & Conquer II

We depend on **recursion** to solve divide & conquer problems

Example: Write pseudocode for the factorial function

```
Direct solution for base case public static int factorial(int n) {
 if (n == 0) return 1;
 else return n * factorial(n-1);
 // post-condition: returns n!
 }
 case
```

Recurrence Relations

It is an **equation** in which a function is defined **in terms of itself**.

Example: Fibonacci(n) = Fibonacci(n-1) + Fibonacci(n-2)

Recursive algorithms can be analyzed using recurrence relations because of that self-reference property

Divide & Conquer Recurrence

$$T(n) = \begin{cases} \Theta(1) & \text{if } n = 1 \\ aT(b) + D(n) + C(n) & \text{otherwise} \end{cases}$$

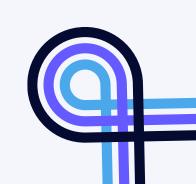

where a is the number of subproblems, b is the size of each subproblem in terms of n, D(n) is the divide time, C(n) is the combine time.

Exercise 3-1 From CLRS (©MIT Press 2001)

Insertion sort can be expressed as a recursive procedure as follows:

In order to sort A[1..n], we recursively sort A[1..n-1] then insert A[n] into the sorted array A[1..n-1]. Write a recurrence for the running time of this recursive version of insertion sort.

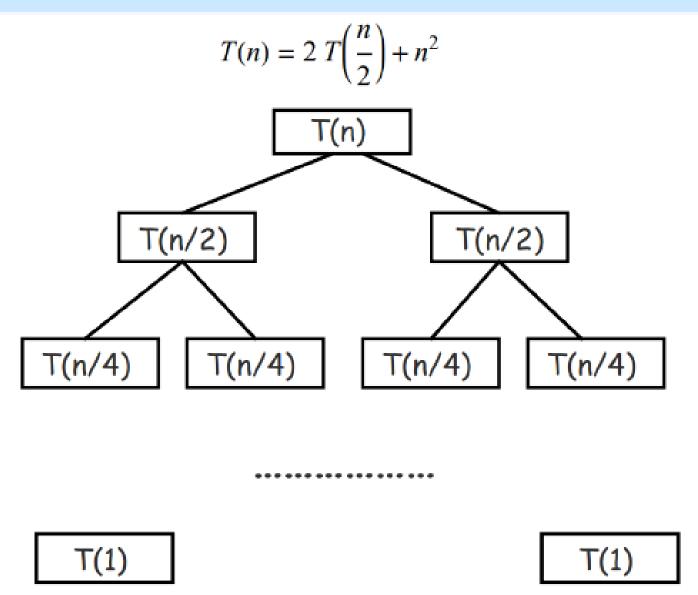

Solving recurrences helps us obtain an upper bound on the running time of the algorithm

We will do this using a Recursion Tree

- Nodes of the tree represent recursive calls
- Root of the tree is the initial call
- Leaves correspond to the exit condition

Tree Method: Steps

- Draw the recursion tree.
- 2 Figure out the height of the tree h.
- 3 Cost of the leaves = number of leaves \times c.
- Figure out a formula representing the cost of each level (possibly in terms of the level number).
- $oldsymbol{6}$ Cost of the rest of the tree $=\Sigma_{i=0}^{h-1}$ cost of each level.
- Total running time = cost of leaves + cost of the rest of the tree.

Exercise 3-2 From CLRS (©MIT Press 2001)

Use a recursion tree to determine a good asymptotic upper bound on the recurrence $T(n) = 3T(\lfloor n/2 \rfloor) + n$.

Exercise 3-4 From CLRS (©MIT Press 2001)

Use the divide-and-conquer approach to write an algorithm that finds the largest item in a list of n items. Analyze your algorithm and get it's worst-case time complexity.

Exercise 3-4 From CLRS (©MIT Press 2001)

Use the divide-and-conquer approach to write an algorithm that finds the largest item in a list of n items. Analyze your algorithm and get it's worst-case time complexity.

```
static int largest( int low, int high ) {
 if ( low == high ) {
    // Subarray size is 1, solution is trivial
    return list[low];
else {
     int mid
               = (low + high) / 2;
    int lLeft = largest( low,  mid );
     int lRight = largest( mid+1, high );
    if ( lLeft > lRight )
        return lLeft;
    else
        return lRight;
```

Exercise 3-5

Write a divide-and-conquer algorithm for the **Towers of Hanoi** problem. The Towers of Hanoi problem consists of three pegs and n disks of different sizes. The objective is to move the disks that are stacked on one of the three pegs (in decreasing order of their size) to a new peg using the third one as a temporary peg. The problem should be solved according to the following rules:

i when a disk is moved, it must be placed on one of the three pegs;

ii only one disk may be moved at a time, and it must be the top disk on one of the pegs; and

iii a larger disk may never be placed on top of a smaller disk.

What is the worst-case time complexity of your algorithm?

```
public class Hanoi {
 enum Tower { A, B, C };
 static void moveDisk( Tower from, Tower to ) {
    System.out.println(
        "Move disk from " + from + " to " + to
    );
public static void towers( int n, Tower x, Tower y, Tower z ) {
    if (n > 0) {
        towers( n-1, x, z, y);
        moveDisk( x, y );
        towers( n-1, z, y, x );
```

All done!
